Options of the individual gingiva treatment in modern implantology

In the field of prosthodontics exist plenty of prefabricated abutments with different gingiva heights and angulations for implant restorations. Especially in challenging gingival situations customized abutments offer an alternative for an optimized emergence profile. This technique requires a forming and contouring of the soft tissue prior to the impression taking for the final restoration.

This report describes different treatment sequences for prefabricated and customized abutments according to the necessary gingiva treatment.
